Warm glow giving theory

ABSTRACT

Peer providers play a crucial role in the growth and sustainability of the sharing economy. However, the psychology and behavior of peer providers who assume the role of suppliers on sharing economy platforms have received insufficient attention in the literature. This study proposes a model that examines the role of warm glow emotion, perceived economic, social, and environmental benefits, and trust beliefs on attitudes and supply intentions on the platform. An online scenario-based survey involving 361 platform users was conducted, and data were analyzed using the partial least squares structural equation modeling technique. The results indicate that warm glow feelings positively influence peer-provider participation. A strong warm glow feeling can also reduce decision-making complexity by enhancing trust and attitudes towards sharing. Perceived social benefits emerge as the strongest predictor of attitudes, followed by trust beliefs and perceived economic benefits; surprisingly, the influence of perceived environmental benefits is dismissed. This study contributes to the sharing economy literature by elucidating the key emotional and psychological factors that precede peer-provider participation. It extends the warm glow-giving theory and emotion literature to contexts beyond charitable and environmental acts. Practical insights are discussed for planning and designing strategies to target peer providers.

1. Introduction

The sharing economy has emerged as a result of significant technological advances and profound social change, reflecting people's increasing use of technology and their growing desire for more efficient, sustainable, and community-oriented approaches to consumption (Botsman & Rogers, 2010; Hira & Reilly, 2017). The sharing economy employs online platforms that enable individuals to interact and collaborate to access and distribute underutilized resources (Choi & He, 2019; Dabić et al., 2024; Eckhardt et al., 2019; Geissinger et al., 2019). It is often credited with providing social, environmental, and economic benefits (Botsman & Rogers, 2010; Frenken & Schor, 2017). However, some scholars debate whether these claims are substantiated (Acquier et al., 2017). This debate underscores the importance of continued academic research to better understand how this innovative model evolves and impacts the economy, people, and the environment (Akande et al., 2020; Böcker & Meelen, 2017; Geissinger et al., 2019).

People's interaction with the sharing economy has progressed significantly over the last decade, accompanied by a substantial expansion of scientific inquiry into this context. However, the literature has paid little attention to the psychology and behavior of individuals who take on supplier roles, also known as "peer providers" (Benoit et al., 2022; Köbis et al., 2021). Eckhardt, Houston, Jiang, Lamberton, Rindfleisch, and Zervas (Eckhardt et al., 2019) describe the sharing economy as a two-sided marketplace that connects individuals who possess underutilized resources with those willing to access them temporarily. While there has been an exponential increase in the demand for sharing economy services, peer providers play a critical role from the supply perspective, enabling others to access resources and services they might not have had previously (Costello & Reczek, 2020). Engaging more peer providers on the platform is crucial to boosting the growth and sustainability of sharing-economy-based models. However, this requires an understanding of the psychological mechanisms behind resource supply behavior on online platforms. Several scholars have suggested that

economic (Boateng et al., 2019; Böcker & Meelen, 2017; Hamari et al., 2016), social (Bernardi & Diamantini, 2018; Cherry & Pidgeon, 2018), and environmental benefits (Böcker & Meelen, 2017; Henry et al., 2021), as well as trust (Hawlitschek, Teubner, & Gimpel, 2018; ter Huurne et al., 2017; Tham et al., 2023; Lu & Yi, 2023; Akin et al., 2021), are important drivers of participation in the sharing economy. However, their effects from the supplier's perspective remain unclear, making this study a unique inquiry.

Another notable research gap involves the role of emotions in sharing economy participation. While previous studies have primarily focused on understanding cognitive and practical factors (e.g., economic, environmental, political, social, and technological factors) (Böcker & Meelen, 2017; Hossain, 2020; Merino-Saum et al., 2023; Rathnayake et al., 2024), less attention has been given to the emotional antecedents of sharing behavior. Sharing resources with others through the platform could be a manifestation of prosocial behavior, driven by emotions of empathy and altruism, recognizing the needs of others, and acting for the greater good (Dunfield, 2014; Luri Minami et al., 2021). However, other scholars contend that individuals engage in prosocial behavior not only out of selfless (pure) altruistic motives but also because it provides them with a sense of personal satisfaction (Andreoni, 1990; Batson et al., 1991). This conception stems from the warm glow-giving theory introduced by Andreoni (Andreoni, 1990), which suggests that people are motivated to engage in prosocial behavior not only by pure altruism but also by impure altruistic reasons or the desire to experience a warm glow. In the sharing economy literature, although some studies emphasize the significance of altruism in sharing resources with others (Hamari et al., 2016; Say et al., 2021), the egoistic aspect of altruistic behavior, or warm glow, has not been thoroughly investigated. Only the work of Schreiner, Pick, and Kenning (Schreiner et al., 2018) discusses the existence of warm glow givers, who are suspected to be more willing to share for the sake of experiencing a warm glow rather than solely for purely altruistic reasons.

Warm glow is a distinct emotional construct that specifically applies to the positive emotional experience of helping others and behaviors that create positive impacts on society and the environment (Andreoni, 1990; Evren & Minardi, 2017; Hartmann et al., 2017; Schneider et al., 2021). Warm glow is distinguished from the broader concept of positive emotions, as the latter encompasses a range of pleasant emotional experiences arising from various events and situations (Fredrickson, 2001; Fredrickson & Branigan, 2005). Therefore, comprehending the emotional factors intertwined with acts of sharing is appropriate when examining the specific phenomenon of warm glow compared to the broader construct of positive emotions. The desire for warm glow influences various behavioral contexts, such as pro-environmental behavior (Hartmann et al., 2017), the purchase of green products (Sun, Hall, & Cegielski, 2020), participation in green programs (Giebelhausen et al., 2016), microlending investments (Allison et al., 2013) and ethical food choices (Iweala et al., 2019). For this examination, the authors find antecedents from extant literature that support aligning the warm glow effect with resource-sharing behavior. Evren and Minardi (Evren & Minardi, 2017) draw on the foundational work of Andreoni (Andreoni, 1990) on warm glow and comment that individuals gain utility not only from the outcomes of their contributions but also from the act of giving itself. Both authors concluded that the transaction between the donor and the act of donation can lead to increased cooperation in resource-sharing scenarios.

It is interesting to note that the notion of warm glow is distinct from altruism, as Stahl and Haruvy (Stahl & Haruvy, 2006) term it "impure altruism," where the giver derives utility not only from the benefits their actions confer on others but also from the act of giving itself. Ferguson and Flynn (Ferguson & Flynn, 2016) agree with the former and opined that a warm glow can coexist with true altruistic motives, leading to a complex interplay of motivations in charitable giving. Furthermore, Jia and van der Linden (Jia & van der Linden, 2020) caution researchers against mistaking warm glow for empathy. The latter can result in warm glow experiences, but it fundamentally involves emotional resonance with another's situation rather than the self-rewarding aspect of the act itself. The above studies provide an impetus to examine the warm glow experience in the context of the sharing economy as a distinct affect.

This study postulates that warm glow is an affective information source that influences the individual cognitions and behaviors of peer providers. The study defines "warm glow" as anticipated positive feelings of joy, pleasure, and satisfaction associated with sharing one's resources on a sharing economy platform. It may facilitate information processing and enhance cognitive abilities (Fredrickson, 2001; Fredrickson & Branigan, 2005; Sinclair et al., 2002). It can also improve an individual's perceptions and evaluations of products and purchasing decisions (Guo et al., 2020; Huang et al., 2022; Jin & Oh, 2021).

While the warm glow-giving theory may explain the emotional rewards derived from impure altruism, it lacks a comprehensive framework to investigate how this effect may translate into intentions. Martín-Santana, Reinares-Lara, and Romero-Domínguez (Martín-Santana et al., 2020) examined donation intention through the joint predictive capacities of anticipated emotions and warm glow giving to offer parsimonious observations about donation intention among active and non-active donor groups. The belief-attitude-intention (BAI) model overcomes these deficiencies by examining certain beliefs about the sharing economy (e.g., trust in the platform, perceived economic benefits, and environmental impact) and incorporates a cognitive layer in estimating intention to share. Finally, this study responds to a call to action by Lv, Shi, Xu, and Wu (Lv et al., 2024), who have encouraged future studies to explore cognitive aspects of the warm glow-giving phenomenon.

Therefore, based on the BAI model (Fishbein & Ajzen, 1975), warm glow-giving theory (Andreoni, 1990), and insights from the emotion literature, this study develops and tests a research model that addresses the following research questions.

RQ1: What factors (e.g., economic, social, and environmental benefits and trust beliefs) predict attitudes and supply intentions on the platform?
RQ2: How does warm glow impact attitudes and supply intentions on the platform?
RQ3: How does warm glow impact the relationship between beliefs and attitudes towards supply intentions on the platform?

This study employed an online scenario-based survey involving 361 individuals with prior usage experience with major sharing economy platforms in the Philippines and gauged their intentions to share a physical resource (i.e., a motorcycle) on a sharing economy platform by assessing their attitudes, warm glow feelings, and other constructs pertinent to the study. Partial least squares structural equation modeling (PLS-SEM) was used to estimate the conceptual model and test the proposed hypotheses.

The current study makes a unique contribution to the literature by advancing the theoretical understanding of the behavioral influence of warm glow beyond acts of charity and environmentalism. The study presents empirical evidence supporting warm glow feelings as a significant affective factor that shapes attitude and supply intentions in the sharing economy. The findings also suggest that warm glow can enhance an individual's perceptions of object attributes and reduce decision-making complexity. Strong feelings of warm glow strengthen the relationship between trust and attitudes towards acts of sharing. This adds to the emotion literature by elucidating how pleasant emotional experiences influence an individual's cognitive processes and subsequent behavior. The study also builds upon the existing sharing economy literature by confirming that economic benefits, social benefits, and trust are reliable predictors of peer provider participation. The study validates Fishbein and Ajzen (Fishbein & Ajzen, 1975)'s BAI model and the multi-attribute model of attitude by elucidating the cognitive and affective predictors of attitude and attitude−intention relations. Most

importantly, the work presents practical insights for developing strategies to foster peer provider engagement in the sharing economy and ensure the long-term sustainability of sharing economy models.

The remaining sections of this paper are organized as follows. First, we present the theoretical background and hypothesis development. Next, we describe the research methodology used in this study. We then present the results and discuss their implications. Finally, we draw conclusions, identify the study's limitations, and suggest future research directions.

2. Literature review and hypothesis development

2.1. Key drivers of sharing economy participation: insights from the literature

Systematic literature review findings suggest that the growth and popularity of the sharing economy can be attributed to its economic, social, and environmental impacts (Khalek & Chakraborty, 2023; Rathnayake et al., 2024). One of the most significant advantages of the sharing economy is that it creates new economic opportunities for people. By sharing resources, individuals can reduce the costs of ownership, earn extra income, and take advantage of employment opportunities. The sharing economy also helps build stronger and more connected communities, as sharing resources encourages collaborative and cooperative behavior, fostering a sense of social connectedness and even forming new relationships. It has also been argued that it can potentially mitigate environmental issues. By using resources more efficiently and reducing waste, the sharing economy can help decrease the need for new production and limit resource depletion.

Furthermore, scholars have underscored the role of trust in sharing economy transactions (Eckhardt et al., 2019; Hawlitschek, Notheisen, & Teubner, 2018). Trust is considered the "currency" of the sharing economy (Botsman & Rogers, 2010), particularly because it involves sharing resources and services with strangers, and using online mediating platforms entails inherent risks. Traditional trust-building mechanisms in conventional economic transactions may not fully apply in the sharing economy; hence, building trust becomes even more crucial (Hawlitschek, Teubner, & Gimpel, 2018). Sharing economy participants must trust each other to engage in mutually beneficial sharing arrangements and establish long-term relationships.

Although the literature highlights the importance of economic, social, environmental, and trust factors for consumer behavior in the sharing economy (Khalek & Chakraborty, 2023; Rathnayake et al., 2024), these studies have primarily focused on the demand perspective (i.e., users accessing resources) (Böcker & Meelen, 2017; Sarkar et al., 2020). Costello and Reczek (Costello & Reczek, 2020) argue that the sharing economy mirrors a two-sided marketplace involving the exchange of goods or services between two distinct actors: 1) peer providers (who offer their resources or services) and 2) consumers or end users (who utilize these resources or services). The platform's value is derived from supply and demand actors, and its success depends on how well it can balance the needs and interests of both sides (Clemens et al., 2025). Popular platforms such as Airbnb or Uber act as intermediaries that connect peer providers with consumers. These platforms create a market by bringing together service suppliers and consumers and facilitating the exchange of goods or services. For example, on Airbnb, hosts (peer providers) offer their homes or apartments for rent, while guests (consumers) use the platform to find and book accommodations.

A further review of the literature suggests that several studies have concentrated on the motivation and behavior of individuals who utilize shared resources (Table 1). Knowledge gaps remain regarding the underlying motives that influence individuals to take on supplier roles in the sharing economy platform. To sustain peer-to-peer sharing and other sharing economy models, it is crucial to have a comprehensive understanding of usage patterns and, most importantly, the mechanisms underlying supply behavior (Jia et al., 2020; Kumar et al., 2018). To address the identified research gap, this study examines the influence of a set of belief factors that are explicitly linked to the sustainability frameworks of the sharing economy (i.e., economic, social, and environmental consequences) and trust towards resource supply intentions on the platform.

2.2. The belief-attitude-intention model of behavior

Fishbein and Ajzen (Fishbein & Ajzen, 1975) proposed the BAI model of behavior, which explains how beliefs, attitudes, and intentions are interconnected and influence one another. *Beliefs* refer to a person's thoughts or opinions about a particular object or behavior, while *attitudes* represent an individual's overall evaluation of that object or behavior based on their beliefs. *Intentions* reflect a person's motivation or willingness to engage in a specific behavior. Specifically, when individuals form beliefs about the likelihood that a particular behavior will lead to favorable outcomes, this influences the formation of a positive attitude towards the behavior, which can then motivate the person to pursue the behavior (intention) (Ajzen, 1991). The BAI framework has been widely utilized in social psychology and applied to various domains, including health, environmental issues, technology adoption, and other behaviors.

In the context of this study, it is posited that attitudes towards sharing are determined by perceived economic, social, and

environmental benefits, as well as trust beliefs, which affect supply intentions on the platform.

2.2.1. Economic benefits

Economic benefits are often considered one of the primary drivers of participation in the sharing economy (Akbari et al., 2022; Akhmedova et al., 2022; Hawlitschek, Teubner, & Gimpel, 2018; Nguyen & Llosa, 2023). Individuals can earn extra income from underutilized or idle resources they share with other users on the platform. This offers economic empowerment (Karlsson & Dolnicar, 2016; Martin, 2016), allowing individuals to earn money from their existing resources (Benoit et al., 2017). Similarly, Laukkanen and Tura (Laukkanen & Tura, 2020) argue that the sharing economy creates employment opportunities, generates secondary incomes, and fosters business ventures that enhance people's economic well-being. Bai and Velamuri (Bai & Velamuri, 2021) emphasize that individuals are more willing to share assets when the economic benefits outweigh transaction costs and the depreciation of holding the asset. Following these arguments, this study posits that individuals may develop a favorable attitude towards sharing in the sharing economy based on their belief that participation can yield economic benefits. This, in turn, may lead to stronger supply intentions on the platform as individuals perceive it as a financially advantageous initiative.

H1. The belief in economic benefit (ECB) positively influences attitudes towards sharing (ATT).

2.2.2. Pro-environmental benefits

Another core promise of the sharing economy lies in its pro-environmental consequences (Botsman & Rogers, 2010; Lang et al., 2022; Schuster et al., 2024). It is argued that, compared to ownership consumption, sharing contributes to waste reduction, extends product lifespans, maximizes product use, and reduces carbon emissions (Botsman & Rogers, 2010; Kathan et al., 2016). Studies have shown that consumers' perceptions of these environmental benefits can influence their willingness to participate in the sharing economy (Merino-Saum et al., 2023; Prieto et al., 2022). Participation in the sharing economy is perceived as a more sustainable option than traditional alternatives for accessing goods and services (Seddighi & Baharmand, 2020; Tham et al., 2023). Böcker and Meelen (Böcker & Meelen, 2017) argue that consumers engage with sharing economy platforms to reduce their environmental impact. Similarly, Luri Minami, Ramos, and Bruscato Bortoluzzo (Luri Minami et al., 2021) found that consumers who recognized the environmental benefits of ride-sharing services were more likely to use them. Li and Tsai (Li & Tsai, 2022) also emphasized that consumers who value environmental sustainability are more likely to trust sharing platforms and engage in sharing activities. Therefore, the belief in environmental benefit (EVB)—the belief that participating in the sharing economy can promote sustainable and pro-environmental outcomes—may shape positive attitudes towards sharing resources and influence supply intentions on the platform. Following these contentions, the following hypothesis is proposed.

H3. The belief in environmental benefit (EVB) positively influences attitudes towards sharing (ATT).

2.2.3. Social benefits

Several scholars note the social consequences of participating in the sharing economy (Cherry & Pidgeon, 2018; Merino-Saum et al., 2023; Rathnayake et al., 2024). Conducting transactions with peers on the platform is considered socially beneficial as it helps create new social ties, strengthen social bonds, and build social relationships (Böcker & Meelen, 2017; Gössling & Michael Hall, 2019; Zhang et al., 2019). Gerwe, Silva, and Castro (Gerwe et al., 2020) emphasize that these social benefits are crucial for providers' decisions to engage in the platform economy. Additionally, Lang, Kemper, Dolan, and Northey (Lang et al., 2022) note that social benefits fuel providers' intrinsic motivation and continued participation, making them feel that they hold a valuable role in the sharing economy ecosystem. However, Schuster, Goseberg, Arnold, and Sundermann (Schuster et al., 2024) posited that social motivations may play a more prominent role than environmental considerations in influencing sharing behavior, depending on the specific context. Therefore, the belief in social benefit (SOB)—the belief that participation in the platform economy confers desirable social consequences—can foster positive attitudes towards sharing resources with others. The study posits the following.

H4. The belief in social benefit (SOB) positively influences attitudes towards sharing (ATT).

2.2.4. Trust belief in the sharing economy platform

Botsman and Rogers (Botsman & Rogers, 2011) state that trust is a vital currency in sharing economy transactions. As Räisänen, Ojala, and Tuovinen (Räisänen et al., 2021) state, "*without trust, there is no sharing*" (p.8). This assertion establishes the idea that trust is fundamental for sharing to occur. Sharing involves giving something of value to another person or entity while often expecting to receive something in return. Without trust, there is a significant risk that the other party may not fulfill their end of the transaction or may exploit the situation in some way. Additionally, because resources are often owned by individuals and used by others, there is a degree of risk involved. For example, when renting out a home or car, there is a risk of theft, property damage, or other types of loss. (Lee et al., 2018). Likewise, when borrowing or renting someone else's personal belongings, there is a risk of damage or loss to the item or harm to the borrower. This lack of trust can make individuals hesitant to engage in sharing activities (Benoit et al., 2017; Gullstrand Edbring et al., 2016), especially with strangers or in situations where there is limited information available about the other party (Cherry & Pidgeon, 2018; Mahadevan, 2018). Therefore, trust is essential for enabling sharing, as it allows individuals to feel more comfortable and secure in engaging in such activities (Lu & Yi, 2023).

Security and privacy issues common to online-mediated platforms also underscore the importance of building trust in the sharing economy (Belanger et al., 2002). Personal and financial information shared on the platform may be vulnerable to hacking or other forms of cyber-attacks, compromising users' security and privacy. Additionally, fraudulent activities, such as fake reviews or identity theft, can undermine users' trust in the platform and other users. Therefore, online-mediated platforms must ensure the security and privacy of their users through technological solutions (Chang et al., 2006).

In response to these trust issues, sharing economy platforms commonly utilize reputation systems and other technological solutions (Räisänen et al., 2021). One example is a system that allows users to rate and review each other based on their experiences. These ratings and reviews are visible to other users. Reputation systems can help identify trustworthy users and discourage fraudulent or malicious behavior. Another approach is identity verification. By verifying users' identities, platforms can hold them accountable for their actions, promoting positive behavior and reducing the likelihood of fraudulent or malicious conduct.

The literature on the sharing economy consistently shows that trust is a key predictor of participation in sharing activities (Ashaduzzaman et al., 2022; Hallem et al., 2021; Hawlitschek, Teubner, & Gimpel, 2018; Lu & Yi, 2023; Rathnayake et al., 2024). Users are more likely to engage in sharing activities if they trust the platform, other users, and the safety and security of their personal information (Quirós et al., 2021; Vaclavik et al., 2020). Studies have found that factors such as reputation systems, identity verification, and other technological solutions are significant for building trust and encouraging participation in the sharing economy.

Based on prior research, the current study suggests that trust positively impacts attitudes towards sharing resources with others on the platform. This study specifically delineates trust as overall trust belief (TRU), which refers to an individual's general level of trust in both other

users of the platform and the platform itself. When individuals possess a higher level of overall trust belief, they are more likely to engage in sharing behaviors, such as renting out their property, because they feel more confident in the safety and reliability of the platform and its users. Conversely, when individuals have a lower level of overall trust belief, they may be more hesitant to share due to concerns about potential risks and uncertainties. Therefore, the study hypothesizes the following.

H5. Overall trust belief (TRU) in the sharing economy platform positively influences attitudes towards sharing (ATT).

2.3. Attitude towards sharing and supply intentions on the platform

According to the BAI model and related frameworks, such as the theory of planned behavior and the theory of reasoned action, an individual's attitude towards a behavior is a significant predictor of their behavioral intentions (Ajzen, 1991; Ajzen & Fishbein, 2000; Conner & Armitage, 1998; Fishbein & Ajzen, 1975). Attitude towards a behavior refers to an individual's overall evaluation or feeling about performing a specific behavior (Ajzen, 1991). An individual develops a positive attitude towards a behavior when it is believed to produce favorable outcomes (Ajzen, 1991; Fishbein & Ajzen, 1975). Behavioral intentions refer to an individual's subjective likelihood of engaging in a particular behavior in the future (Ajzen, 1991; Fishbein & Ajzen, 1975). They represent an individual's readiness to perform a behavior and are influenced by the individual's attitude towards that behavior. Studies have validated the links between attitude and behavioral intentions in various contexts (Armitage & Conner, 2001). Behavioral intention is arguably a proximal determinant of actual behavior (Conner et al., 2020), while attitude towards a behavior is the best predictor of behavioral intentions (Armitage & Conner, 2001; Bagozzi, 1981; Zaremohzzabieh et al., 2021). Building on this knowledge, the study posits the following.

H6. Attitudes towards sharing (ATT) positively influence supply intentions in the sharing economy platform (INT).

2.4. Theory of warm glow giving

Batson (Batson, 1987) and Batson, Batson, Slingsby and Harrell (Batson et al., 1991) propose that, in addition to pure altruism, egoistic motives play a role in prosocial behaviors. They argue that people are driven to engage in prosocial behavior to help others selflessly and because it generates a positive emotional experience for the giver/-helper. Positive emotions may be associated with acts of empathy, which is the ability to understand and share the feelings of others (Batson et al., 1991). When people see others in need and respond with acts of kindness or generosity, they may experience a sense of connection and positive emotion as a result. Andreoni (Andreoni, 1989) and Andreoni (Andreoni, 1990) introduced warm glow-giving theory, which elucidates the impure altruistic motivations behind charitable behaviors. The theory explains that when individuals donate money to a charity, they desire a positive emotional feeling known as "warm glow." People continue to participate in charitable giving because they enjoy the positive emotional experience that accompanies it. Scholars propose that warm glow can encompass both aspects: it can be the positive affect anticipated before engaging in a particular behavior, and it can also be experienced as an emotion resulting from the actual engagement in that behavior (Mayo & Tinsley, 2009; Schneider et al., 2021). Harbaugh, Mayr, and Burghart (Harbaugh et al., 2007) argue that warm glow results from activating the brain's reward system, which regulates emotions and motivation. They suggest that when people engage in charitable behavior, this system is activated, and individuals experience a positive emotional response. Warm glow also derives from a sense of fulfillment or satisfaction from knowing that contributions help improve the welfare of other people, groups, communities, or the environment (Hartmann et al., 2017).

Conceptions of the warm glow-giving theory have primarily focused on prosocial acts that do not involve explicit tangible rewards. Studies have considered warm glow an emotional construct and elucidated its role in prosocial behaviors and contexts such as pro-environmental behavior (Hartmann et al., 2017), green purchase behavior (Sun, Wang, et al., 2020), Sun, Wang, et al., 2020 and ethical food choices (Iweala et al., 2019). Within the realm of the sharing economy, characterized by a unique blend of profit-driven motives and prosocial orientation (Böcker & Meelen, 2017), knowledge of the impact of the intrinsic reward of warm glow emotions on sharing behaviors among peer providers remains limited. To address this research gap, this study proposes that the motivation to experience warm glow serves as a driving force for individuals to engage in sharing behaviors, facilitating the sharing of assets and the provision of assistance to those in need, ultimately creating a positive impact on people's lives.

Studies have identified the prosocial implications of the sharing economy (Abutaleb et al., 2023; Bäro et al., 2022; Küper & Edinger-Schons, 2020). Since the sharing economy involves peers sharing resources and assets, this may translate to the greater good of the community or the environment (Botsman & Rogers, 2011; Frenken & Schor, 2017; Hamari et al., 2016). The sharing economy may promote a sense of community and encourage individuals to work together to meet each other's needs. Sharing initiatives can also reduce waste, save money, and promote sustainability. Additionally, the sharing economy can provide opportunities for individuals who may not have the means to access certain resources. With these potential contributions, scholars explain how prosocial motives can help shape behaviors in the sharing economy (Costello & Reczek, 2020; Hamari et al., 2016). However, some scholars oppose the idea that pure altruism is the primary motivation behind collaborative (sharing) behaviors. Instead, they propose that impure altruism may be the driving force. For example, Schreiner, Pick, and Kenning (Schreiner et al., 2018) argue that the willingness to share assets in the sharing economy is motivated not by altruism but by warm glow feelings.

Very few studies have explored the emotional factors associated with sharing economy behaviors. These studies include the work of Hamari, Sjöklint, and Ukkonen (Hamari et al., 2016), as well as Hawlitschek, Teubner, and Gimpel (Hawlitschek, Teubner, & Gimpel, 2018), Hawlitschek, Notheisen, & Teubner, 2018nd Huang and Kuo (Huang & Kuo, 2020) on the role of enjoyment or hedonic rewards, which is conceptualized differently from warm glow. Warm glow differs from the broader concept of positive emotion (Fredrickson, 2001; Fredrickson & Branigan, 2005) as it is other-focused and driven by a desire to do good for others and make a positive impact. It is associated with a sense of satisfaction that one's actions can make a positive difference for others, society, and the environment. The emphasis on emotions in the sharing economy has primarily centered on the viewpoint of individual users. Consequently, investigating the influence of the warm glow phenomenon on supply intentions among peer providers would reveal novel emotional aspects of sharing economy behavior.

Within the context of this study, the term "warm glow" refers to the anticipated positive feelings of joy, pleasure, and satisfaction associated with sharing one's resources (assets) in the sharing economy. Supplying resources on the platform may be viewed as a common good behavior that contributes to the well-being of others, communities, and the environment, thus producing positive emotions. Specifically, this study regards warm glow as an emotional predictor of attitude. Research on attitudes highlights the role of affective factors in shaping attitude formation. For instance, Eagly, Mladinic, and Otto (Eagly et al., 1994) propose that affective information sources, in addition to cognitive information, contribute to attitude development. Similarly, Allen, Machleit, Kleine, and Notani (Allen et al., 2005) emphasize that incorporating emotional experiences (affect) along with cognitive (belief) variables enhances the prediction of attitudes. Based on this understanding and recognizing warm glow as an emotive variable, this study hypothesizes the following.

H6. Warm glow (WGG) positively influences attitudes towards sharing (ATT).

2.5. Moderating role of warm glow

Warm glow, a specific type of positive emotion, may exhibit a moderating impact mechanism similar to how affective information sources or positive emotions adjust cognition and behaviour (Eagly et al., 1994; Edell & Burke, 1987). Scholars such as Fredrickson (Fredrickson, 2001) argue that positive emotions can help individuals become more open to new experiences, thoughts, and ideas, enhancing creativity, flexibility, and resilience in the face of challenges. Sinclair, Ashkanasy, Chattopadhyay, and Boylee (Sinclair et al., 2002) suggest that positive emotions can facilitate cognitive processing, improving abilities such as attention, memory, and creativity. Griskevicius, Shiota, and Neufeld (Griskevicius et al., 2010) note that positive emotions may lead to either more heuristic or more systematic processing compared to an emotionally neutral state.

A further synthesis of the emotion literature indicates that positive emotions can significantly shape how individuals perceive the consequences of their behavior and influence their motivation to pursue specific actions. For instance, Lerner and Keltner (Lerner & Keltner, 2000) reveal the role of emotions in risk assessments, arguing that individuals experiencing negative emotions tend to perceive greater levels of risk in their environment. Conversely, positive emotions can boost optimism and decrease the perceived risk of unfavorable outcomes. This suggests that when individuals experience positive emotions, they may be more likely to focus on potential positive outcomes and underestimate risks or negative consequences. For example, Huang, Zhu, Hao, and Deng (Huang et al., 2022) found that positive emotions help reduce the complexity and vulnerability of online shopping decisions. When individuals feel positive emotions while shopping online, they may feel more optimistic, relaxed, and in control, making the experience more enjoyable and less stressful. Guo, Wang, and Wu (Guo et al., 2020) also argue that positive emotions can lead to more favorable product evaluations. When individuals experience positive emotions, they are more likely to evaluate a product positively, resulting in more favorable attitudes towards the product. Supporting this claim, Jin and Oh (Jin & Oh, 2021) found that positive emotions elicited by an interactive website led individuals to evaluate the website interface more positively, thereby influencing their attitude and intention to engage with the site.

Building on insights from the emotion literature, this study posits that warm glow, a positive emotional state arising from helping others (e.g., sharing), can enhance individuals' perception of the benefits (i.e., economic, social, environmental) and trust associated with acts of sharing in the sharing economy. This, in turn, reinforces stronger positive attitudes toward sharing resources on the platform. Therefore, this study proposes the following.

H7a. High WGG strengthens the ECB → ATT relationship.

H7b. High WGG strengthens the EVB → ATT relationship.

H7c. High WGG strengthens the SOB → ATT relationship.

H7d. High WGG strengthens the TRU → ATT relationship.

The research model is presented in Fig. 1.

3. Methodology

3.1. Sample population

The study recruited individuals aged 18–44 in the Philippines, a demographic that includes digital natives such as Gen Z and millennials (Pew Research Center, 2020). These age groups are the primary participants in the sharing economy (Kumar et al., 2018). It has been reported that Gen Z and millennials constituted 68 % of new Airbnb hosts in 2021 in the Philippines (Airbnb, 2021).

The Philippines exhibits a thriving sharing economy dominated by mobility, accommodation, and food-sharing platforms. The transportation sector has been led by ride-hailing platforms such as Grab and Angkas, which allow individuals to share rides with others for a fee (Maderazo, 2023, p. 100). In the accommodation industry, platforms like Airbnb and Agoda have become popular, enabling property owners to rent unused spaces to tourists and travelers (Tumbali, 2020). Food delivery services such as Foodpanda and GrabFood have also thrived, allowing individuals to share their cooking skills with others and deliver these skills to customers (Rakuten Insight, 2022). The impact of the sharing economy on the country's economy is significant. For instance, a

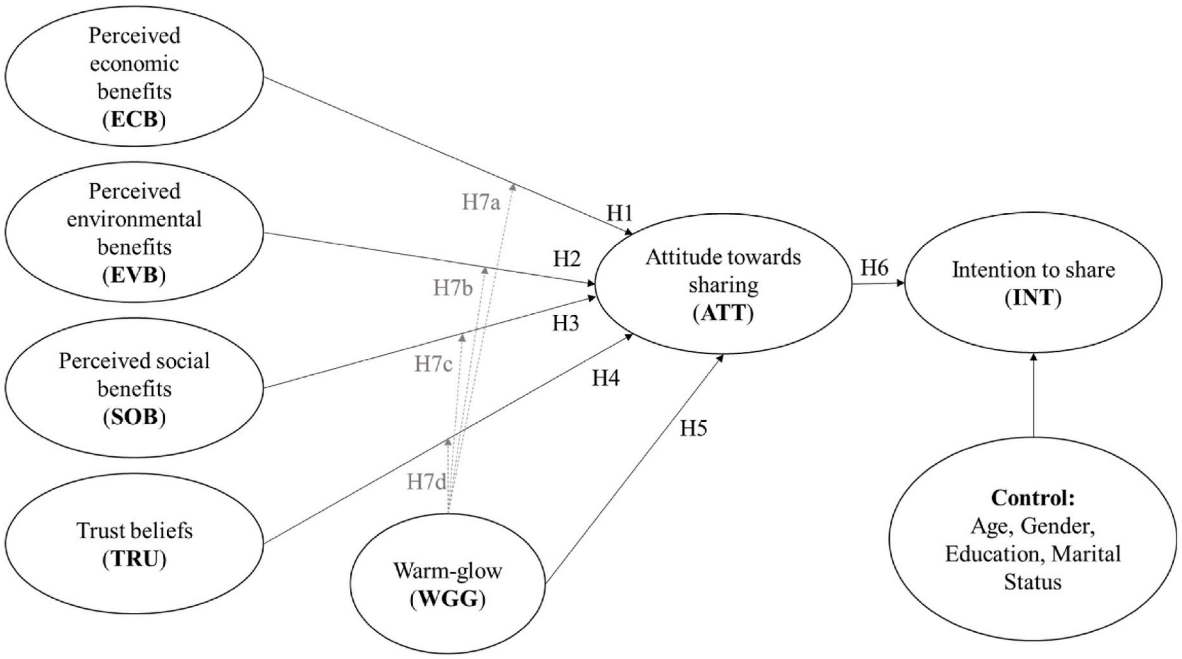

Fig. 1. The research model.

2019 Oxford Economics study commissioned by Airbnb estimated that hosting activities contributed USD 1 billion to the country's gross domestic product and generated over 160,000 jobs (Airbnb, 2021). Furthermore, the market volume for car-sharing and bike-sharing is expected to reach USD 47.65 million and USD 51.41 million, respectively, by 2027 (Statista, 2023). In terms of the country's internet economy, valued at 1.87 trillion Philippine pesos (Philippine Statistics Authority, 2022), the sharing economy constitutes approximately 38 %, according to estimates reported by Balbieran and Mabbagu (Balbieran & Mabbagu, 2022).

To ensure that study participants were well-informed about the sharing economy concept, they were filtered based on their past usage of sharing economy services. After obtaining their consent to participate, a list of sharing economy platforms was provided, and they were asked to indicate which platforms they had used at least once. Those who had not used any sharing economy platforms were excluded. Ultimately, 361 respondents had prior usage experience with major sharing economy platform operators such as Grab (81 %), Angkas (28 %), Airbnb (20 %), Foodpanda (20.1 %), Upwork (15.9 %), and Kickstarter (4.3 %). The respondents' profiles are detailed in Table 2.

3.2. Survey design

A scenario-based survey was designed for data collection. Participants were instructed to imagine themselves deciding to share a physical asset (i.e., a motorcycle) on a sharing economy platform. Motorcycles are a popular mode of transportation in the Philippines, where there are over 7.81 million registered motorcycles (Statista Research Department, 2023). They are more affordable than cars, making them more accessible to Filipinos. Moreover, with the rise of large platform companies offering motorcycle ride-hailing and delivery services in the country, such as GrabBike, Angkas, and JoyRide, sharing motorcycles through these platforms has become a viable option.

A pictorial webpage of a fictitious sharing platform was provided, containing information about how the platform worked and promotional content highlighting the benefits and implications users could expect when transacting on the online platform (see Appendix A). Subsequently, participants were asked to respond to questions gauging their intentions to share the item and other constructs pertinent to the study.

The study operationalized the constructs through validated scales from prior studies with minor adaptations to fit the study context. The behavioral intention (INT) and attitude (ATT) scales were adapted from Ajzen (Ajzen, 1991), while items measuring belief factors were adopted from multiple sources: economic benefits (ECB) (Bucher et al., 2016; Fota et al., 2019; Gazzola et al., 2019; Tussyadiah et al., 2015), environmental benefits (EVB) (Fota et al., 2019; Hamari et al., 2016), social benefits (SOB) (Gazzola et al., 2019; Heijden, 2004), and trust (TRU) (Fota et al., 2019; Gefen, 2000; Mittendorf et al., 2019; Schreiner et al., 2018). Measures of warm glow giving (WGG) were adapted from Hartmann, Eisend, Apaolaza, and D'Souza (Hartmann et al., 2017), which were drawn from scales measuring positive affective rewards (Bagozzi et al., 1999; Edell & Burke, 1987). All constructs were gauged on a 5-point Likert scale (1–strongly disagree to 5–strongly agree).

It is worth noting that while the measures for ATT and WGG are conceptually distinct, a natural theoretical relationship exists between them. Attitude items focus on cognitive evaluations of sharing behavior (Ajzen, 1991) (e.g., "*Sharing the item with people in need is a good thing*", ATT3). In contrast, warm glow items capture the emotional rewards derived from sharing (Hartmann et al., 2017; Konrath & Handy, 2018) (e.g., "*Sharing the item makes me feel pleased to be doing something good*", WGG3). Although these constructs may show some correlation, they measure different psychological processes—evaluative judgments versus affective responses.

The survey was structured into different sections, beginning with a brief description of the survey and the sharing economy concept, an assessment of familiarity and past usage, scenario exposure, and measurements of supply intentions, attitudes, and other pertinent constructs. The original English translations of the items were retained, corresponding to the official language in the Philippines. Consultations with professors and researchers experienced in conducting survey research were performed to ensure the quality of the survey questionnaire. For further quality control, pretests were conducted to ensure the comprehensibility of the questions among respondents.

The survey invitations were sent online through direct messages to targeted participants on various social media platforms. The absence of a sampling frame constituting peer providers prompted the use of a convenience sampling procedure. While acknowledging the shortcomings of a nonprobabilistic sample (Bornstein et al., 2013), its use remains pertinent as this study sought to achieve analytic rather than population-based generalization (Kwarteng et al., 2022; Polit & Beck, 2010). Additionally, given the study's initial theory-testing focus, we drew upon Ashraf and Merunka (Ashraf & Merunka, 2017) arguments suggesting that convenience samples may still be viable despite the need to validate findings with a more representative and heterogeneous sample in future research. Furthermore, to capture only "informed" participants and secure reliable self-reports, screening based on their past usage of sharing economy services was performed.

Table 2
Respondents' profile (n = 361).

Age	n	%	Marital Status n		%
18–24	314	87.00	Married	26	7.20
25–34	32	8.90	Separated	1	0.30
35–44	15	4.20	Single	334	92.50
Educational Attainment			**Gender**		
Less than high school	1	1.00	Woman	207	57.30
High school graduate	34	34.00	Man	130	36.00
Some college	182	182.00	Transgender	1	0.30
2 year degree	29	29.00	Non-binary/non-conforming	3	0.80
4 year degree	77	77.00	Prefer not to respond	20	5.50
Professional degree	5	5.00			
Doctorate	2	2.00			
Master's degree	31	31.00			

3.3. Controls for common method bias

Common method bias (CMB) is a prevalent threat in most survey-based research. According to Kock, Berbekova, and Assaf (Kock et al., 2021) and Podsakoff, MacKenzie, Lee, and Podsakoff (Podsakoff et al., 2003), CMB arises when systematic variance in the data is attributable to the data collection method rather than the constructs being measured. These authors also indicate that CMB occurs when the same method is used to measure both independent and dependent variables in a study, leading to a spurious correlation between them. CMB threatens the reliability and validity of empirical results; thus, it is imperative to adopt measures to control for these issues in the research. The study employed procedural and statistical measures to control for CMB, as suggested by Kock, Berbekova, and Assaf (Kock et al., 2021). The procedural controls included: 1) using multi-item measures of dependent and independent variables from diverse sources, 2) ensuring response anonymity, providing clear survey instructions, and using comprehensible question items, and 3) separating the measures of the dependent and independent variables proximally.

Harman's single-factor test dismissed serious CMB issues, as the cumulative variance of the first factor extracted was 35.92 %, which was below the 50 % acceptable threshold (Podsakoff et al., 2003). Using the full collinearity test suggested by Kock (Kock, 2015), the results also indicated that the model was free from CMB, as the variance inflation

factor (VIF) scores were lower than 3.3. Finally, to address endogeneity issues, several control variables were included in the model: gender, age, and educational attainment. The results suggested that their inclusion did not modify the significant effects of attitude on intentions. Using SmartPLS4 software, the Gaussian copula approach was performed to test for endogeneity in the model. No significant copulas were detected, effectively ruling out serious endogeneity concerns (Hult et al., 2018; Sarstedt et al., 2020).

3.4. Data analysis

PLS-SEM was used to estimate the conceptual model and test the proposed hypotheses due to the study's exploratory nature, the structural configuration of the research model, and the use of non-normal data. Astrachan, Patel, and Wanzenried (Astrachan et al., 2014) and Dash and Paul (Dash & Paul, 2021) have noted that PLS-SEM offers better prediction and explanation than its covariance-based (CB-SEM) counterpart, particularly for theory development studies using nonmetric data and small sample sizes. The approach also demonstrates greater flexibility in dealing with complex structural models involving mediation and moderation configurations (Dash & Paul, 2021). Despite critiques, researchers across disciplines have widely used and supported this analytical approach (Hair et al., 2019).

To mitigate potential biases associated with non-applicable SOB items, several measures were implemented during the data analysis phase. First, data cleaning and screening processes were conducted to remove incomplete or inconsistent responses, ensuring the quality of the dataset. Second, statistical adjustments were performed to verify the robustness of the constructs across the sample. These steps aimed to enhance the accuracy of the findings and reduce the likelihood of biases stemming from item-specific non-applicability.

4. Results

4.1. Measurement model assessment

Following the guidelines of Hair, Howard, and Nitzl (Hair et al., 2020), the measurement model was evaluated based on several reliability and validity indicators (Table 3). Initially, the standardized loadings were examined and revealed that the values exceeded the threshold of 0.708 and were significant at $p < 0.01$. Reliability checks using the metrics of composite reliability (CR) and Cronbach's alpha (α) revealed satisfactory results, as the values were above 0.70. Furthermore, the convergent validity of the constructs was established, as the average variance extracted (AVE) values exceeded 0.50. The constructs also exhibited sufficient discriminant validity based on the Fornell and Larcker (Fornell & Larcker, 1981) criterion and the heterotrait-monotrait ratio of correlations (HTMT). The square root of the AVE of each construct was higher than its correlation with other constructs (Fornell & Larcker, 1981), and the HTMT ratios met the cut-off scores of 0.85 and 0.90 (Hair et al., 2020) (Table 4). Further examination of the cross-loadings showed that all items loaded appropriately on their respective constructs (Table 5).

4.2. Structural model assessment and hypothesis testing

An initial step in the structural model assessment involved examining multicollinearity issues (Hair et al., 2020). The results dismissed

Table 3
Constructs, items, and assessment of the measurement model.

	Loadings	Mean	σ	Cronbach's alpha	Composite reliability	AVE	VIF
Intention to share fashion clothing (INT) (Ajzen, 1991)				0.799	0.882	0.713	
INT1: If the circumstances allow it, I will share the item in the future.	0.848	3.90	0.93				1.823
INT2: It is likely that I will share the item with others through the website.	0.834	3.54	0.96				1.692
INT3: Given a chance, I predict that I will share the item in the near future.	0.851	3.77	0.91				1.894
Attitude toward sharing fashion clothing (ATT) (Ajzen, 1991)				0.773	0.855	0.596	
ATT1: Sharing the item with others through the website is a wise move.	0.802	3.53	1.00				1.643
ATT2: Sharing the item with other people via the website is a positive thing.	0.768	3.61	0.94				1.579
ATT3: Sharing the item with people in need is a good thing.	0.705	4.31	0.90				1.220
ATT4: Sharing the item with others via the platform makes sense.	0.808	3.83	0.95				
Economic benefits (ECB) (Bucher et al., 2016; Fota et al., 2019; Gazzola et al., 2019; Tussyadiah et al., 2015)				0.878	0.916	0.732	
ECB1: I share the item via the website because it pays me money.	0.847	3.68	1.08				2.189
ECB2: Sharing item via the website allows me to make money from something I own.	0.869	3.96	1.03				2.392
ECB3: Earning extra money is an important factor when sharing the item through the website.	0.857	3.98	1.01				2.393
ECB4: Sharing the item via the website is a good way to supplement my income.	0.850	3.85	1.01				2.296
Environmental benefits (EVB) (Fota et al., 2019; Hamari et al., 2016)				0.913	0.939	0.792	
EVB1: Sharing the item via the platform helps save natural resources.	0.880	3.90	1.01				2.585
EVB2: Sharing the item through the platform is sustainable.	0.879	3.84	0.96				2.874
EVB3: Sharing the item via the platform is ecological.	0.919	3.75	0.97				3.891
EVB4: Sharing the item through the platform is environmentally friendly.	0.881	3.81	0.98				2.765
Social benefits (SOB) (Gazzola et al., 2019; Heijden, 2004)				0.827	0.896	0.741	
SOB1: It is enjoyable to share the item to other people via the website.	0.874	0.95	0.95				1.790
SOB2: Sharing the item through the website make me feel like part of a community.	0.867	0.95	0.95				1.982
SOB3: Sharing allows me to gain unique social experiences through meeting interesting people.	0.842	0.99	0.99				1.848
Trust (TRU) (Fota et al., 2019; Gefen, 2000; Mittendorf et al., 2019; Schreiner et al., 2018)				0.838	0.891	0.671	
TRU1: The sharing website provides a robust and safe environment.	0.809	3.31	0.91				1.768
TRU2: The sharing website is trustworthy.	0.844	3.09	0.92				2.021
TRU3: Even if not monitored, I'd trust the people with whom I share the item I own.	0.806	2.80	1.02				2.410
TRU4: I generally trust other people using the item I share on the platform.	0.818	2.93	0.96				2.408
Warm-glow giving (WGG) (Hartmann et al., 2017; Konrath & Handy, 2018)				0.909	0.936	0.785	
WGG1: Sharing the item gives me a pleasant feeling of personal satisfaction.	0.876	3.34	1.04				2.197
WGG2: Sharing the item makes me feel happy.	0.887	3.56	1.03				2.517
WGG3: Sharing the item makes me feel pleased to be doing something good.	0.874	3.72	0.99				2.256

Notes: [d] – item dropped due to low factor loading, Abbreviations: AVE – average variance extracted; VIF – variance inflation factor.

Notes: cross-loadings (diagonal, in bold).

severe multicollinearity issues, as the variance inflation factor (VIF) scores of all combinations of endogenous and exogenous constructs were higher than 0.20 and lower than 5 (Hair et al., 2017).

A complete bootstrapping procedure with 5000 subsamples was performed to estimate the size and significance of the path coefficients and test the proposed hypotheses. The complete results are presented in Table 6 (also see Appendix B). It was found that ECB ($\beta = 0.146$, t = 2.699, $p < 0.01$), SOB ($\beta = 0.271$, t = 3.863, $p < 0.001$), TRU ($\beta = 0.237$, t = 3.990, $p < 0.001$), and WGG ($\beta = 0.130$, t = 2.340, $p < 0.05$) exerted significant positive effects on ATT. These results provided support for H1, H3, H4, and H5. Only the effect of EVB on ATT was not significant, leading to the rejection of H2. ATT had a significant positive effect on INT (β = 0.714, t = 19.206, p < 0.001), supporting H6.

Moreover, the moderation analysis revealed that WGG had a significant positive moderating effect only on TRU→ATT ($\beta = 0.105$, t = 2.07, $p < 0.05$). This supports H7d while rejecting H7a, H7b, and H7c. The simple slope analysis depicted in Fig. 2 further suggests that when WGG is high, the relationship between TRU and ATT is stronger.

Upon further analysis, it was found that the research model explained 36.5 % of the variation in attitude toward sharing, while 46.7 % of the variation in sharing intentions was accounted for (Table 7). The R^2 values exceeded 20 %, indicating robustness for social science research (Carranza et al., 2020; Hair et al., 2017). The influence of ATT on INT was observed to have a large effect size (f^2), whereas other parameter relationships exhibited small effect sizes. The model also displayed strong predictive relevance, with $Q^2_{predict}$ statistics greater than

0 (Leong et al., 2021; Shmueli et al., 2019). Moreover, only a small number of the dependent construct indicators had RMSE prediction errors that exceeded the naïve LM benchmark, suggesting that the model had moderate predictive power according to Hair, Howard, and Nitzl (Hair et al., 2020).

5. Discussion and conclusion

Despite scholars' interest in understanding consumers' participation in the sharing economy, attention has primarily focused on the receiving end, such as users accessing shared goods and services. Knowledge of peer providers' participation and their underlying motivations remains scarce (Akhmedova et al., 2022; Benoit et al., 2017; Gupta et al., 2019). The dual-market characteristic of the sharing economy underscores the importance of addressing the needs and desires of both consumers and providers to generate value for both parties. Moreover, given the exponential increase in demand for sharing economy services, efforts to engage more peer providers to supply additional goods and services on the platform are crucial (Boysen et al., 2019; Kumar et al., 2018). A distinct feature of this study is its examination of the role of warm glow emotions and their moderating effect on cognition–attitude relations among individuals who supply resources in the sharing economy more readily. The study also investigates the effects of perceptions of economic, social, and environmental benefits, as well as trust beliefs (previously identified as relevant drivers from the demand perspective), on individuals who take on supplier roles in the sharing economy.

The study highlights the significant positive effect of warm glow feelings on attitudes towards sharing and intentions to supply on the platform. This finding corroborates claims from other behavioral contexts, such as pro-environmental behavior, energy conservation, and charitable giving (Chaabouni et al., 2021; Hartmann & Apaolaza-Ibáñez, 2008; Mimouni Chaabane & Parguel, 2016; Sun, Wang, et al., 2020). Scholars assert that the desire for warm glow motivates acts of kindness and generosity (Andreoni, 1990; Hartmann et al., 2017). This study demonstrates that this emotional experience also manifests in sharing resources with others on the platform. A provider may supply a resource to help others, but this act also generates pleasant and satisfying emotions. These positive feelings may lead individuals to hold positive attitudes towards sharing their possessions and, ultimately, their intention to share. This finding addresses the speculations of Schreiner, Pick, and Kenning (Schreiner et al., 2018) regarding the potential role of warm glow in people's willingness to share goods in the sharing economy. It is further argued that in addition to the expectation of monetary incentives in return for sharing possessions, individuals also anticipate experiencing warm glow by sharing their resources and contributing to the community.

Another distinctive finding reveals that warm glow can moderate the relationship between belief factors (economic, social, environmental, and trust) and attitudes towards sharing. This study found that warm glow can strengthen the connection between trusting beliefs and attitudes. This means that when individuals experience more positive feelings about sharing, they are more likely to believe that others and the platform are trustworthy, thereby increasing their support for sharing activities. To the best of the authors' knowledge, this evidence has not been previously presented in the sharing economy literature. This finding aligns with the contention from the emotion literature that positive emotional experiences can broaden individuals' attentional focus, improve decision-making, and increase motivation (Fredrickson & Branigan, 2005). Jin and Oh (Jin & Oh, 2021) supported this idea by emphasizing that positive emotional experiences can lead to better assessments of a website interface and promote positive behavior towards it. Guo, Wang, and Wu (Guo et al., 2020) also found that when individuals feel positive emotions during purchases, they perceive products and services more favorably and feel more inclined to buy them. These authors demonstrated that positive emotions make the shopping process feel less complex and overwhelming, reduce feelings of vulnerability, and help build trust and confidence. Considering these ideas in the context of this study, it is reasonable to suggest that experiencing a warm glow can facilitate trust in the sharing of goods and lead to more positive attitudes towards acts of sharing.

Surprisingly, among other predictors tested in the research model, the findings indicate that perceived social benefits strongly impact attitudes towards sharing. This finding contradicts the assertion made by Hüttel, Ziesemer, Peyer, and Balderjahn (Hüttel et al., 2018) that social motives play a less significant role in sharing economy participation and diverges from the prevailing view that economic benefit is the strongest driver of sharing economy participation (Alaei et al., 2022; Hawlitschek, Teubner, & Gimpel, 2018). Hence, this study concludes that positive social outcomes are more influential than tangible rewards (e.g., monetary incentives) (Böcker & Meelen, 2017; Gerwe et al., 2020). The significance of social benefits implies that if someone lends possessions on a platform and enjoys interacting with users/borrowers, they may develop a more positive attitude towards sharing possessions. Sharing economy platforms can facilitate interactions between individuals who may not otherwise cross paths, creating opportunities for social engagement. Interactions among transacting peers elicit socially beneficial rewards, such as the enjoyment of meeting new people, forming social connections, and fostering feelings of community belonging (Cherry & Pidgeon, 2018; Zhang et al., 2019).

Consistent with prior evidence, trust in the platform remains a significant factor influencing attitudes and supply intentions on platforms, which aligns with the claims of Lu and Yi (Lu & Yi, 2023), Ashaduzzaman, Jebarajakirthy, Weaven, Maseeh, Das, and Pentecost (Ashaduzzaman et al., 2022), Hallem, Abbes, Hikkerova, and Taga (Hallem et al., 2021), and Hawlitschek, Notheisen, and Teubner (Hawlitschek, Notheisen, & Teubner, 2018). A trusting belief in the platform and peers is crucial for sharing resources (Gullstrand Edbring et al., 2016; Hawlitschek et al., 2016) and serves as an important currency in sharing economy transactions (Botsman & Rogers, 2010). When individuals have higher levels of trust in the sharing platform and other users, they are more likely to participate as peer providers. Due to the risks involved in online transactions, potential loss, and the risk of physical damage to shared possessions, it is essential to ensure that online platforms can be trusted and, most importantly, that strangers seeking access to products and services can be trusted (Lee et al., 2018). When people trust the online platform to handle payments and disputes fairly, they are more likely to feel comfortable using it. Similarly, if they can trust other users to treat their resources with respect and adhere to the platform's rules, they are more likely to be willing to share their resources with others. Trust is more easily established through reputation-based systems and other technological solutions adopted by sharing economy platforms (Räisänen et al., 2021). Additionally, the digital natives, as demonstrated by the study sample, exhibit greater openness to transacting online and engaging in business model innovations (Herrando et al., 2019), allowing them to build trust in the sharing economy.

Perceived economic benefits remain a significant predictor of attitudes and supply intentions on platforms. This finding corroborates existing claims that economic incentives (e.g., cost savings or earning additional income) drive sharing economy participation, not just among users but also for peer providers (Böcker & Meelen, 2017; Gazzola et al., 2019; Rathnayake et al., 2024; Tham et al., 2023; Wilhelms et al., 2017). Monetizing underutilized possessions helps working individuals supplement their incomes and offers income-generating opportunities for those who may not have access to traditional forms of employment. Thus, the sharing economy can be viewed as a way to facilitate economic empowerment among individuals (Martin, 2016).

Botsman and Rogers (Botsman & Rogers, 2010) and Frenken and Schor (Frenken & Schor, 2017) note the pro-environmental promises of the sharing economy. They show that sharing practices facilitate efficient resource utilization, reduce waste, and curtail the rapid depletion of scarce natural resources. Empirical evidence suggests that

environmental motivations influence sharing economy participation (Hamari et al., 2016; Luri Minami et al., 2021; Merino-Saum et al., 2023; Morschheuser et al., 2016, pp. 4375–4384). Surprisingly, this study found that beliefs associated with the sharing economy's environmental consequences did not affect attitudes towards sharing and supply intentions on platforms. Notably, the sharing economy's pro-environmental consequences remain a subject of debate and are yet to be fully understood by consumers (Cherry & Pidgeon, 2018; Ratilla et al., 2021), which plausibly explains this insignificant effect. There exists a divergent notion that the sharing economy produces rebound effects that can potentially harm rather than benefit the environment (Warmington-Lundström & Laurenti, 2020). People may not perceive their actions as significantly impacting the environment, leading them to prioritize other factors. Moreover, the strong commercial emphasis of popular sharing economy platforms compels individuals to prioritize economic or social gains over environmental benefits when deciding to share resources.

While this study adopts a general perspective to enhance the generalizability of its findings, it acknowledges that responses may differ significantly across product categories in the sharing economy. For instance, platforms for accommodations may evoke stronger social and economic benefits due to the interpersonal nature of hosting (Nguyen & Llosa, 2023), compared to transportation-sharing platforms where trust and efficiency may take precedence (Möhlmann, 2015). Similarly, peer providers sharing services may prioritize economic benefits more than emotional drivers (Arteaga-Sánchez et al., 2020). The study aligns itself with existing investigations by Zhu and Grover (Zhu & Grover, 2022) and Dorahaki, Rashidinejad, MollahassaniPour, Pourakbari Kasmaei, and Afzali (Dorahaki et al., 2023), who have employed a similar scenario-based survey design in the context of the sharing economy.

5.1. Theoretical contributions

This study bridges the gap in the literature concerning the factors that lead to and the motives behind peer providers' participation in the sharing economy.

A noteworthy contribution of the study is that it provides empirical evidence on the role of warm glow emotions in the intention of peer providers to supply resources on platforms. The warm glow reflects the positive emotional experience of doing something good and has been found by scholars to influence giving behaviors (Andreoni, 1990). To date, no studies have empirically examined the role of warm glow in supply behaviour in the sharing economy; hence, this study is one of the first to offer such evidence. Existing conceptions of the warm glow-giving theory are largely represented by behaviors that do not involve tangible rewards. Donations and prosocial and environmental behaviors are often driven by the desire for intrinsic rewards rather than explicit expectations of receiving monetary compensation. Within the context of the sharing economy, the dynamics of behavior differ, particularly when considering the supply of resources among peer providers on the platform. In this unique setting, the motivations for sharing can encompass both extrinsic and intrinsic reward expectations. Therefore, this study offers further insights into warm glow-giving theory beyond prosocial and charitable behaviors. It is argued that, in addition to extrinsic reward expectations (i.e., monetary compensation from sharing underutilized resources), individuals who desire emotionally positive feelings from sharing will be inclined to supply resources on the platform.

Moreover, this study contributes novel insights to the literature on the moderating mechanisms of warm glow on belief-attitude relations. Warm glow, as a distinct emotional construct, enhances individuals' perceptions of objects' attributes and helps reduce decision-making complexity. A high level of warm glow strengthens the relationship between trust and attitudes towards sharing, suggesting that experiencing warm glow can increase people's trust perceptions regarding sharing goods and potentially result in more favorable attitudes towards sharing behavior. This adds to the emotion literature by elucidating ways in which pleasant emotional experiences influence an individual's cognitive processes and subsequent behavior.

The work also validates Fishbein and Ajzen's (Fishbein & Ajzen, 1975) BAI model and underscores the cognitive and affective factors that shape attitudes and behavioral intentions in the sharing economy context. Attitude remains the best predictor of behavioral intentions, while cognitions of social and economic benefits and trust beliefs precede attitudes regarding the act of sharing. This study also contributes insights into the multi-attribute attitude model by specifying that the warm glow emotion is a significant affective predictor of attitude. Finally, this study builds upon the current literature on the sharing economy by affirming that economic benefits, social benefits, and trust are reliable indicators of participation in the sharing economy for both consumers and peer providers. However, the role of environmental motivations in driving sharing economy participation remains a subject of debate.

5.2. Practical contributions

This study offers valuable insights for platform providers, particularly in designing strategies to encourage individuals to assume supplier roles on sharing economy platforms. This approach is essential for ensuring the growth and sustainability of sharing economy models in the long run. The study proposes that strategies targeting peer providers should focus on promoting positive social experiences, economic benefits, trust, and fostering feelings of warmth and fulfillment.

One effective way to enhance social incentives in the sharing economy is by facilitating increased interaction and communication among peers before, during, and after transactions, whether through online or offline channels. Additionally, creating social groups and organizing events that encourage users and providers to connect, interact, and discuss shared interests can foster a sense of belonging, thereby enhancing social incentives. It is also necessary to provide appropriate monetary incentives for sharing resources on the platform. Additional incentives, such as discounts on transaction fees and bonuses for top-performing providers, can further enhance the appeal of economic benefits and motivate both existing and potential providers to supply goods and services. Offering educational resources, such as customer service training, can improve service quality, enhance providers' performance and ultimately lead to greater economic incentives.

Moreover, several methods can cultivate trust in both the platform and the users of shared goods. One approach is for platform providers to adopt secure payment systems to prevent fraud and ensure that providers receive payment for their services. Platforms could also verify users' identities to promote transparency and accountability. Offering insurance or liability coverage is imperative to reduce fears and risks associated with unexpected losses or damage to shared possessions. The availability of dispute resolution services can be helpful in cases of conflicts between providers and users. Integrating reviews and ratings into platforms can provide valuable information about the reliability of both providers and users.

Most importantly, it is crucial to generate feelings of warmth and fulfillment to promote peer providers' participation in the sharing economy. One way to achieve this is by emphasizing the positive outcomes associated with acts of sharing on the platform. Platforms can showcase the benefits of participating as a peer provider, such as helping individuals with limited access to resources, contributing to environmental sustainability, promoting economic empowerment, and fostering community engagement. Participants may consequently experience joy, pleasure, and fulfillment from contributing to such causes.

Ultimately, the findings of this study can be applied across various product categories. In accommodations, platforms like Airbnb can enhance trust through identity verification and advanced cleaning services while stimulating feelings of warmth by emphasizing cultural

exchange and community building. For ridesharing services (e.g., Uber, Grab), platforms can prioritize economic benefits through flexible work hours and dynamic pricing, cultivate trust with safety certifications and background checks, and highlight drivers' contributions to community accessibility. Furthermore, in equipment rental platforms, clear liability policies are essential, alongside social benefits like community events and a focus on sustainable consumption through resource sharing. These product category-specific strategies provide valuable guidance for practitioners and researchers in optimizing peer-to-peer platforms.

5.3. Limitations and future research directions

This study has several limitations that future research can address. First, caution is advised in generalizing the results, especially since sharing intentions and their predictors were assessed for a specific physical asset type (i.e., a motorcycle). Future studies should validate the model with other physical asset types and resources, such as skills, talent, time, finances, and energy. To account for socioeconomic and cultural biases and to address sampling issues, it is recommended to replicate the study using a more diverse and representative demographic group and populations from different regions. Second, examining whether sharing intentions manifest as actual behaviors would be a fruitful area for future investigation. It is also imperative to track behaviors over time to better understand behavioral patterns, which could inform interventions to sustain peer providers' participation. Third, it is important to note that the SOB items (belief in social benefit) may not have been fully applicable to all respondents, particularly those who may not have experienced the scenarios described. While efforts were made to mitigate biases through rigorous data cleaning and statistical adjustments, the potential for residual biases remains. Future studies should consider refining the design of SOB items to ensure greater applicability across diverse respondent profiles. This could include pretesting the items with representative samples to identify and address potential ambiguities before full-scale data collection. Fourth, this study relied on self-report measures of warm glow, which may not accurately capture the full range and complexity of emotional experiences associated with sharing. Although several studies have used and validated these measures, a more precise assessment would incorporate physiological measures (e.g., EEG, fMRI), behavioral indicators (e.g., facial expressions, vocal intonation), and ecological momentary assessment methods. Finally, this study adopts a general perspective to enhance the generalizability of its findings. Future research could build on these findings by conducting comparative analyses across different product types and examine how the interplay of perceived benefits, trust, and emotional factors varies. Such an approach would provide richer insights for platform providers aiming to tailor strategies to specific market segments and product categories.
